

# Statistical Assumptions and Properties of the OLS estimator

- SLR.1  $y_i = \beta_0 + \beta_1 x_i + u_i \quad i = 1 \dots n$
- SLR.2  $\{(x_i, y_i), i = 1 \dots n\}$  is a random sample
- SLR.3  $\sum (x_i - \bar{x})^2 > 0$
- SLR.4  $E(u_i | x_1, x_2, \dots, x_n) = 0 \quad i = 1 \dots n$
- SLR.3'  $\sum (x_i - \bar{x})^2 > 0$  and  $\{x_i\}$  are fixed in repeated sampling

Rks:

- SLR.2 says that the observations are all independent.
- SLR.4 says that each disturbance is mean independent of *all* the explanatory variables  $x_i$ . With SLR.2, this reduces to  $E(u_i|x_i) = 0$ .
- SLR.3 is usually strengthened to SLR.3' in economics. This allows us to treat the explanatory variables as fixed numbers and strictly speaking guarantees SLR.4. In practice, economists view SLR.4 as the crucial assumption, and invoke SLR.3' just to avoid saying "conditional on  $X$ ". This is a worthwhile simplification but it should not confuse you!

:Properties of  $\hat{\beta}_1$  under SLR.1-SLR.4

$$\hat{\beta}_1 = \frac{\sum (x_i - \bar{x})y_i}{\sum (x_i - \bar{x})^2} \quad (*) \quad \text{by SLR.3}$$

$$= \frac{\sum (x_i - \bar{x})(\beta_0 + \beta_1 x_i + u_i)}{\sum (x_i - \bar{x})^2} \quad \text{by SLR.1}$$

$$= \frac{\beta_0 \cdot 0 + \beta_1 \sum (x_i - \bar{x})x_i + \sum (x_i - \bar{x})u_i}{\sum (x_i - \bar{x})^2}$$

$$= \beta_1 + \sum_i \left( \frac{x_i - \bar{x}}{\sum (x_i - \bar{x})^2} \right) u_i$$

$$\equiv \beta_1 + \sum_i w_i u_i \quad (**)$$

Rks:

- The weights satisfy  $\sum w_i = 0$  and  $\sum w_i^2 = 1 / \sum (x_i - \bar{x})^2$
- (\*) is the formula used to compute the estimator
- (\* \*) is the formula used to derive the sampling properties

:Expected value of  $\hat{\beta}_1$

Define  $\underline{x} = (x_1, x_2, \dots, x_n)$ .

$$\begin{aligned} E(\hat{\beta}_1 | \underline{x}) &= \beta_1 + E\left(\sum_i w_i u_i | \underline{x}\right) \\ &= \beta_1 + \sum_i w_i E(u_i | \underline{x}) \quad \text{given } w_i = f(\underline{x}) \\ &= \beta_1 + 0 \quad \text{by SLR.4} \end{aligned}$$

$\therefore$  SLR.1-SLR.4  $\Rightarrow \hat{\beta}_1$  is conditionally unbiased (given  $\underline{x}$ ).

Rks:

- $E(\hat{\beta}_1) = E\left[E(\hat{\beta}_1 | \underline{x})\right] = E(\beta_1) = \beta_1$ . So conditionally unbiased implies unbiased.
- Prove  $E(\hat{\beta}_0) = \beta_0$ .

: Variance of  $\hat{\beta}_1$

- SLR.5  $Var(u_i|\underline{x}) = \sigma^2$  (conditional homoskedasticity)

Rks:

- In presence of SLR.2, SLR.5 is equivalent to  $Var(u_i|x_i) = \sigma^2$
- If  $Var(u_i|x_i) = \sigma^2(x_i)$  we have conditional heteroskedasticity
- Because  $Var(u_i) = E[Var(u_i|\underline{x})] + Var[E(u_i|\underline{x})]$ , with random sampling we always have unconditional homoskedasticity ( $Var(u_i)$  is a constant)!

From

$$\hat{\beta}_1 = \beta_1 + \sum_i w_i u_i$$

We get

$$\begin{aligned} \text{Var}(\hat{\beta}_1 | \underline{x}) &= \sum_i w_i^2 \text{Var}(u_i | \underline{x}) + 2 \sum_{i < j} w_i w_j \text{Cov}(u_i, u_j | \underline{x}) \\ &= \sum_i w_i^2 \text{Var}(u_i | x_i) && \text{by SLR.2} \\ &= \sum_i w_i^2 \sigma^2 && \text{by SLR.5} \\ &= \frac{\sigma^2}{\sum (x_i - \bar{x})^2} \end{aligned}$$

Rks:

- In general,  $Var(\hat{\beta}_1|\underline{x})$  is much more interesting than  $Var(\hat{\beta}_1)$ . But under SLR.3', (i.e. the regressors are "fixed"), then these two objects are the same. In economics, we often write  $Var(\hat{\beta}_1) = \sigma^2 / \sum (x_i - \bar{x})^2$  even though we know the regressors are not fixed.

Definition: For SLR, OLS estimator of  $\sigma^2$  is

$$\hat{\sigma}^2 = \frac{1}{n-2} \sum \hat{u}_i^2$$

Under SLR.1-SLR.5,  $E(\hat{\sigma}^2) = \sigma^2$ . (proof with ch3)

Definition: The "standard error of the regression" is

$$\hat{\sigma} = \sqrt{\hat{\sigma}^2}$$

Definition: The "standard error of  $\hat{\beta}_1$ " is its estimated standard deviation, i.e.

$$s.e.(\hat{\beta}_1) = \sqrt{\frac{\hat{\sigma}^2}{\sum (x_i - \bar{x})^2}}$$

Rk: In ch 3, we'll go beyond first two moments of the OLS estimators.

# Statistical Properties using Matrix Notation

## :Preliminaries

### a. Expectation of a random matrix

Let  $Y$  be an  $(m \times n)$  matrix of r.v.'s, i.e.  $Y = (y_{ij})$  where  $y_{ij}$  is a r.v.

Definition:  $E(Y) \in \mathbb{R}^{m \times n}$  with  $[E(Y)]_{ij} = E(y_{ij})$

$$\text{Ex: } Y = \begin{bmatrix} y_{11} & y_{12} \\ y_{21} & y_{22} \end{bmatrix} \quad E(Y) = \begin{bmatrix} E(y_{11}) & E(y_{12}) \\ E(y_{21}) & E(y_{22}) \end{bmatrix}$$

Properties: Suppose  $Y^1$  and  $Y^2$  are  $(m \times n)$  matrix of r.v.'s, and  $A^i \in \mathbb{R}^{p \times m}$ ,  $B^i \in \mathbb{R}^{n \times r}$  for  $i = 1, 2$ . Then

- $E(A^1 Y^1 B^1 + A^2 Y^2 B^2) = A^1 E(Y^1) B^1 + A^2 E(Y^2) B^2$

## b. Covariance matrix

Let  $y$  be an  $(m \times 1)$  vector of r.v.'s.

Definition: The covariance matrix of  $y$ ,  $V(y) \in \mathbb{R}^{m \times m}$ , is given by

$$V(y) = E((y - Ey)(y - Ey)')$$

- $y - Ey$  is an  $(m \times 1)$  vector of centered r.v.'s, and its outer product is the  $(m \times m)$  matrix of r.v.'s given by

$$\begin{aligned}
 & (y - Ey)(y - Ey)' \\
 = & \begin{bmatrix} y_1 - Ey_1 \\ \vdots \\ y_m - Ey_m \end{bmatrix} \begin{bmatrix} y_1 - Ey_1 \cdots & y_m - Ey_m \end{bmatrix} \\
 = & \begin{bmatrix} (y_1 - Ey_1)^2 & \cdots & (y_1 - Ey_1)(y_m - Ey_m) \\ \vdots & \ddots & \vdots \\ (y_m - Ey_m)(y_1 - Ey_1) & \cdots & (y_m - Ey_m)^2 \end{bmatrix}
 \end{aligned}$$

Therefore,

$$V(\mathbf{y}) = \begin{bmatrix} \text{var}(y_1) & \cdots & \text{cov}(y_1, y_m) \\ \vdots & \ddots & \vdots \\ \text{cov}(y_1, y_m) & \cdots & \text{var}(y_m) \end{bmatrix}$$

So  $[V(\mathbf{y})]_{ij} = \text{cov}(y_i, y_j)$

- a.k.a. the "variance-covariance" or the "dispersion" matrix
- $V(\mathbf{y})$  is symmetric.

Properties: Suppose  $\mathbf{y}$  is an  $(m \times 1)$  vector of r.v.'s,  $\mathbf{a} \in \mathbb{R}^m$ , and  $B \in \mathbb{R}^{r \times m}$  (or  $B \in \mathbb{R}$ ).

- 1.  $V(\mathbf{a} + \mathbf{y}) = V(\mathbf{y})$
- 2.  $V(B\mathbf{y}) = BV(\mathbf{y})B'$

:Sampling distribution of  $\hat{\beta}$

I will rewrite the statistical assumptions slightly as

- S1  $y_i = \beta_0 + \beta_1 x_i + u_i \quad i = 1 \dots n$
- S2  $\sum (x_i - \bar{x})^2 > 0$
- S3  $E(u_i | x_1, x_2, \dots, x_n) = E(u_i | \underline{x}) = 0 \quad i = 1 \dots n$
- S4  $E(u_i u_j | \underline{x}) = \delta_{ij} \sigma^2$  where  $\delta_{ij}$  is Kronecker's delta fn.
  - a)  $\forall i \quad E(u_i^2 | \underline{x}) = \sigma^2$
  - b)  $\forall i \neq j \quad E(u_i u_j | \underline{x}) = 0$

Rks:

- SLR.1  $\Leftrightarrow$  S1
- SLR.3  $\Leftrightarrow$  S2
- SLR.2 and SLR.4  $\Rightarrow$  S3
- SLR.2 and SLR.5  $\Rightarrow$  S4

:In matrix notation

- S1  $y = X\beta + u$
- S2  $X'X$  is invertible
- S3  $E(u|X) = 0$
- S4  $V(u|X) = \sigma^2 I_n$

Using S1 and S2

$$\begin{aligned}\hat{\beta} &= (X'X)^{-1}X'y \\ &= (X'X)^{-1}X'(X\beta + u) \\ &= \beta + (X'X)^{-1}X'u\end{aligned}$$

Define  $L = (X'X)^{-1}X'$ ,  $P = X(X'X)^{-1}X'$ ,  $M = I - P$

:First Moment

$$\begin{aligned} E(\hat{\beta}|X) &= E(\beta + Lu|X) \\ &= \beta + LE(u|X) \\ &= \beta \quad \text{by S3} \end{aligned}$$

:Second Moment

$$\begin{aligned} V(\hat{\beta}|X) &= V(\beta + Lu|X) \\ &= V(Lu|X) \\ &= LV(u|x)L' \quad \text{by S4} \\ &= (X'X)^{-1}X'(\sigma^2I_n)X(X'X)^{-1} \\ &= \sigma^2(X'X)^{-1}X'X(X'X)^{-1} \\ &= \sigma^2(X'X)^{-1} \end{aligned}$$
